

MedLens Trust Report

Query: ("creatine" AND "monohydrate" AND "supplementation") AND ("exercise" OR "physical activity")
Verdict: Low risk

The scientific evidence suggests that creatine monohydrate supplementation is relatively well tolerated and produces beneficial effects in various populations, including athletes, older adults, and patient populations. Creatine supplementation has been consistently shown to have positive effects on short-duration, high-intensity exercise activities. The evidence also suggests potential beneficial effects on brain health and function, particularly in aging adults or during times of metabolic stress.
